

Project Overview

Credit Score Classification

Built multi-model classifiers to **assign customers to poor / standard / good credit categories and explore drivers of credit quality**. Dataset: 100,000 observations, 21 variables spanning demographics, financial metrics, and payment behavior; no missing data, so modeling proceeds without imputation bias. Compared multinomial/ordinal logistic regression with tree-based models.

Objective: Classify credit score categories and identify influential predictors of financial behaviour.

Approach: Exploratory analysis → train multinomial & ordinal logistic, decision tree, random forest; compare performance and interpretability

Validation: Train/hold-out evaluation with standard classification metrics; model choice guided by comparative performance and interpretability.
